

Special tokens in NLP

Common special tokens in NLP

Token	Meaning / Use
<pad>	Padding to make sequence the same length in a batch size
<eos>	End of sentence (marks where text stops) \Rightarrow stops GPT generation
<bos>	Beginning of sentence (used in some models to indicate start)
<unk>	Unknown token (used for words not in vocab)
<cls>	classification token (used in BERT for sentence lvl tasks) Ex I love Pizza \Rightarrow <cls> I love Pizza (BERT would add cls to start) • cls represents whole sentence. after encoding, the vector for cls is used for tasks like, sentiment classification, topic classification etc.
<sep>	Separator (splits sentences or segments in a sequence) helps separate different segments in sentence like making QA pairs Ex <cls> how are you? <sep> i am fine. cls \Rightarrow represents whole input for classification, <sep> \Rightarrow marks boundary between Q and A (sep = segment separator)
<mask>	Masked tokens (used for masking tokens see p120)

[Ex: Categorical Focal cross entropy loss]

focal loss functions

Binary cross entropy \rightarrow Categorical cross entropy

focal loss is a modification to standard cross entropy loss functions (mainly BCE / CCE) to specifically handle extreme class imbalance problems

- in a standard approach (CCE) the loss is for multi class classification (ie to imv classes) CCE calculates error based on how far model predictions where from true label it gives the same weight to all errors treating all easy and hard examples the same for ex. if 1 class has no defects in imv the model quickly learns to guess no defect most of the time this massive number of correct predictions dominate total loss burying gradients needed to learn defective classes
- The focal loss approach introduces a modulating factor $(1-p_t)^{\gamma}$ the cross entropy function this factor dynamically scales the contribution of each example to the overall loss forcing model to prioritize learning from hard examples. p_t = predicted prob for correct class
• γ (gamma usually 2.0) focus param controls down weighting

EX: EX type	model confidence p_t	modulating factor $(1-p_t)^\gamma$	Effect	Ex2: true label \Rightarrow A																
easy (majority class)	High (ex 0.99)	very small (ex $0.01^2 = 0.0001$)	Loss becomes negligible	Model pred prob \Rightarrow A: 0.95, B: 0.03, C: 0.02 p_t (prob true class) = 0.95																
hard (minority class)	Low (ex 0.01)	close to 1 (ex $0.9^2 \approx 0.81$)	loss remains high forcing focus	<table border="1"> <thead> <tr> <th></th> <th>metric</th> <th>calc</th> <th>value</th> </tr> </thead> <tbody> <tr> <td>CCE loss</td> <td>$-\log(p_t)$</td> <td>$-\log(0.95) \approx 0.051$</td> <td></td> </tr> <tr> <td>modulating factor</td> <td>$(1-p_t)^\gamma$</td> <td>$(1-0.95)^2 \approx 0.00012$</td> <td></td> </tr> <tr> <td>Focal loss</td> <td>CCE loss \times Factor</td> <td>0.051×0.00012</td> <td>≈ 0.000012</td> </tr> </tbody> </table>		metric	calc	value	CCE loss	$-\log(p_t)$	$-\log(0.95) \approx 0.051$		modulating factor	$(1-p_t)^\gamma$	$(1-0.95)^2 \approx 0.00012$		Focal loss	CCE loss \times Factor	0.051×0.00012	≈ 0.000012
	metric	calc	value																	
CCE loss	$-\log(p_t)$	$-\log(0.95) \approx 0.051$																		
modulating factor	$(1-p_t)^\gamma$	$(1-0.95)^2 \approx 0.00012$																		
Focal loss	CCE loss \times Factor	0.051×0.00012	≈ 0.000012																	

Result: the model was super confident (high p_t) meaning it has already learned this example so we scale the loss down and vice versa so millions of easy ex don't dominate gradients (learning).
